# *Smart TV Hacking*

January 2013

Nikos Sidiropoulos

Periklis Stefopoulos

## *Abstract*

Modern TV technology demands a far more advanced and typical entertainment system. The idea behind the “Smart TV” concept is the ability of this system to interact with the Internet. However, the more “Smart” the TV is, the more network related services it provides, and the more likely it is to be vulnerable to remote attacks. Given the above statement, we focused on revealing these vulnerabilities and subsequently abusing them. Specifically, we managed to perform an online firmware upgrade by impersonating Samsung’s update servers. Additionally, we discovered that the browser’s TLS/SSL implementation was bad leading to a successful man in the middle attack. Finally, we document all the other design flaws that were found, in terms of security and formulate corresponding threat scenarios.

## ***Acknowledgements***

# *1 Introduction*

Smart TVs are considered as a mandatory entertainment system tailored to the average user which can be placed to a typical home/office network. These systems have several functionalities:

- Content delivery like photos, movies and music from other computers or network attached storage devices
- Network interfaces (Ethernet & Wi-Fi).
- Usb interfaces for keyboard/mouse/storage devices.
- Access to Internet-based services like video and audio streaming, as well as social apps.
- Web browsing with usb keyboard/mouse support.
- Remote control apps for smartphones, tablets and PCs.
- Video/audio interaction for the high end models.

This kind of entertainment system demands to have a proper operating system (stripped down Linux based OS). It is equipped with a CPU (ARM based), RAM, Flash-storage and EEPROM. Similarly with smartphones and tablets, most of the Smart TVs can be updated via Internet or USB. As most of the latest Smartphone OSs demand an application repository, Smart TVs are no exception in this rule. Every manufacturer has created its own “app store” where the users can install, uninstall and update their apps according to their needs. Given that some of the apps deal with private information, vendors are expected to create devices that are secure enough in order to prevent unauthorized access to the TV and block active and passive attacks from hackers.

- This unauthorized access permits the TV acting in different modes:
  - ✓ As a Trojan horse to the home network.
  - ✓ As a stealth surveillance camera/mic service.
  - ✓ As a botnet.
- Passive attacks permit eavesdropping of sensitive data.
- Active attacks permit impersonation (MiTM attack).

Based on the fact that Smart TVs are rather popular in homes, offices, educational institutes and public areas (cafes), our purpose is to investigate the level of security of a Smart TV and assess the security risks. Specifically, our model of reference will be a Samsung TV, due to its large market share (almost 25%)<sup>1</sup>

A Smart TV is considered unsecure due to the following reasons: Firstly, there is no shell access provided to the user, which makes the identification of an attack almost impossible. Secondly, there is no antivirus created for Smart TVs and - even if existed - it wouldn't make the product more secure. In any case, it is proposed that vendors should provide secured devices without any intervention from a third party. Hence, the following question and sub-questions arise:

“What kinds of security countermeasures are implemented in a Samsung Smart TV?”

- Are they enough in order to characterize the Smart TV secure?
- Are there any vulnerabilities? If so, how can we misuse them?

Our approach is based on remote attacks and not on attacks requiring physical access to the device. A remote attack is far more challenging as a method, since it can be applied both in a single and in a multi-attack scenario.

The structure of this paper is as follows: At first, the Materials and Methods are stated, followed by the Vulnerability Analysis where the major (Firmware Attack-Browser Attack) and minor attacks (Miscellaneous Attack) are discussed. Furthermore, there is a short Discussion in which all the design flaws and their consequences are presented. The Conclusion chapter provides answers to the research question while the Future Work section gathers our ideas concerning all further research work which needs to be done.

<sup>1</sup> [http://www.koreatimes.co.kr/www/news/biz/2012/10/309\\_114056.html](http://www.koreatimes.co.kr/www/news/biz/2012/10/309_114056.html)

## *2 Materials and Methods*

### *2.1 Materials*

#### **Hardware:**

- Samsung Smart TV UES5500 Out of the Box
  - ARMv7 microprocessor
  - Firmware 1029
  - Linux based OS (2.6.17 - 2.6.36)
  - Flash Disk : 1 GB
  - Interfaces
    - USB, HDMI, Ethernet, CI,UART
- Linksys WRT54G → DDWRT
- Sony Vaio Laptop → Windows 7
- Samsung Laptop → Linux Ubuntu 12.04
- Samsung Galaxy S
- Samsung Galaxy Note

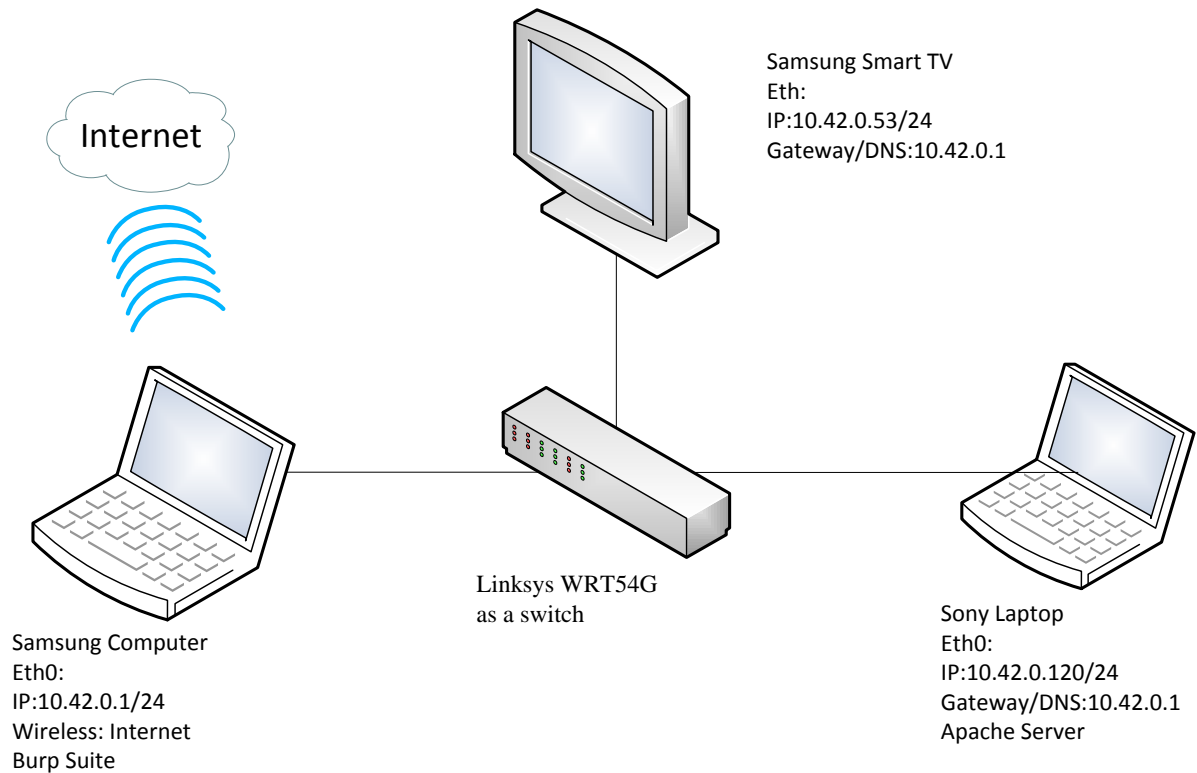

#### **Software:**

- Nessus Home Edition
- Burp Suite
- Wireshark
- Zenmap
- Txc-ssl-dos
- Nikto
- DirBuster

## 2.2 Methods

The following topology diagram was applied for our experiments:

**Figure 1: Topology diagram**

A straightforward and self-explanatory topology is applied. The Samsung Laptop is connected through Wi-Fi Access to the Internet and serves as a router DHCP and DNS. Linksys WRT54G acts as a switch where the Smart TV and the Sony laptop are connected.

## ***3 Vulnerability Analysis***

The aim of this research paper is to find new vulnerabilities or expand vulnerabilities that have been already found. The scheme of black box approach was followed. Initially, based on the technical characteristics of the TV, six areas which could possibly reveal vulnerabilities were identified: Firmware, Browser, Samsung Apps, Remote Help Management, AllShare and Remote Control. Moreover, additional tools like, Zenmap and Nessus, were used to further complete our research. More emphasis was given to the first two research areas in which the major weaknesses were revealed.

### ***3.1 Firmware Attack***

#### ***3.1.1 Firmware Importance***

The firmware is the core element of any electronic system comprising of persistent memory, program code and data. In the case of the Smart TV, the firmware is the operating system which is responsible for managing the TV's available hardware resources and providing common services to the programs needed for the TV.

#### ***3.1.2 About the Firmware***

The running version of the TV's firmware is 1029, while 1030 and 1031 updates are available through Samsung's product support site<sup>2</sup>. Samsung does not provide any kind of change log to the versions it provides through its website. There are three update procedures that can be followed:

- On line (Internet)
- USB
- Broadcast signal

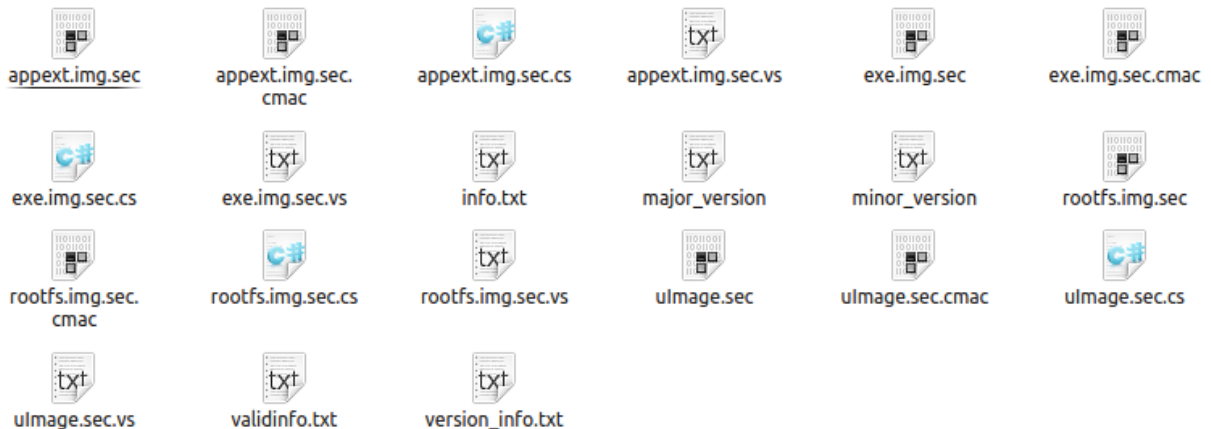

---

<sup>2</sup> <http://www.samsung.com/uk/support/model/UE32ES5500KXXU-downloads>

### 3.1.3 Vulnerability Assessment

The firmware does not provide any kind of shell access, so from that point of view it seems secure yet unmanageable from the user perspective. But, what if you can modify the firmware, in order to get root access<sup>3</sup>, and install it by using any of the aforementioned update procedures? How does Samsung prevent such a thing to happen? All the firmwares available for download and installed via USB are encrypted but not in the best possible way as it turned out. The encryption method (two-layered encryption: AES + XOR) was proven insufficient. A development team from Samygo.tv has created a tool for decrypting/encrypting most of the Samsung TV firmwares<sup>4</sup>. Additionally, for every file in this firmware update package (USB update) there is also another file that contains a cmac signature (figure 2). This signature guaranties the integrity and authenticity of the firmware. Hence, the TV's USB update procedure requires a firmware that is cryptographically signed by Samsung.

Figure 2 USB firmware files

---

<sup>3</sup> Root access means full access to all features that the TV provides like file system, usb ports, Ethernet, microphone, camera etc.

<sup>4</sup> [http://wiki.samygo.tv/index.php5/Extracting\\_the\\_ES-series\\_firmware](http://wiki.samygo.tv/index.php5/Extracting_the_ES-series_firmware)

Using the `SammyGoFirmwarePacher.py`<sup>5</sup> the firmware was decrypted (Figure 3) and the following files were derived.

Figure 3 USB decryption process

```

<sup>5</sup> <http://sourceforge.net/p/samygo/code/HEAD/tree/patcher/trunk/SamyGO%20Firmware%20Patcher.py>

The uImage is the “VDLinux” based kernel image, while rootfs.img and appext.img are the file system and auxiliary data/programs images respectively. The most important image is the exe.img because it contains the exeDSP which is the main executable for running the digital signal processor (DSP). The next step was to mount those images and inspect them thoroughly. Exe.img contains rc.local which defines the booting order of the system as well as the different types of libraries being used. The folder WIFI\_LIB contains the drivers supported for Wifi hardware as well as the iperf tool. Moreover, the Java folder has all the supported java libraries. In the following figure (Figure 5) the whole exe.img file structure is depicted.

Figure 5 exe.img files

APPDATA_IMG_VER	gemstar	libShadowSS.so	samsung_mstar.ko	stagecraft
BT_LIB	Images	libUTOPIA.so	SAVINA	stagecraft20
CM_LIB	InfoLink	LifeScenario	SAVINA_T2	starts.sh
Comp_LIB	IRAN	otpcheck.sh	SDMA	SubMi.comEU.bin
Demo	JadeTarget.cfg	partition.txt	SDMA_AU	SubMi.comUS.bin
EDID	Java	PBA	SDMA_NZ	SUWON
EepromCleaner.sh	lib	PCM	SDMA_SG	SUWON_AU
EepromCleaner_X10P	libEGL.so	PhotoBrowser	SEH	SUWON_TW
exeDSP	libGLSv1_CM.so	prelink.cache	SEIN	Transponder
EXE_IMG_VER	libGLSv2.so	prelink.conf	SERK	TSE
Factory_Part1.dat	libMali.so	rc.local	SESK	TSED
Factory_Part2.dat	libOpenVG.so	ReleaseInfo	SIEL_C	TTSEC
FastLogo	libOpenVGU.so	resource	SIEL_N	Upgrade
Fastlogo.sh	libSDAL.so	Runtime	SmartTV	WebServerApp
GAME_LIB	libSDAL.so.1	samsung_mali.ko	SpecialItemNumber.txt	WIFI_LIB

By mounting rootfs.img it was possible to view the whole filesystem structure (Figure 7). Most of the folders are symbolic links that point the common read/write area (mtd\_rwcommon) which is the “sandbox” for the apps. By exploring “/etc/” we can find rc.local which reveals all the mountpoints.

Figure 6 /etc/rc.local

```

By investigating the “/bin” folder enabled us to understand what types of commands are available. All these commands are linked(symbolic) to busybox.

Figure 8 /bin

```
ash      cat      cttyhack dmesg  grep    ls      mv      ping   sed     sync
authuld  chmod   date     echo  hostname mkdir  netstat ps     sh     touch
awk      chown   dd       egrep kill    mknod  nice   pwd    sleep  umount
busybox  cp      df       fgrep ln      mount  pidof  rm     stty   usleep
```

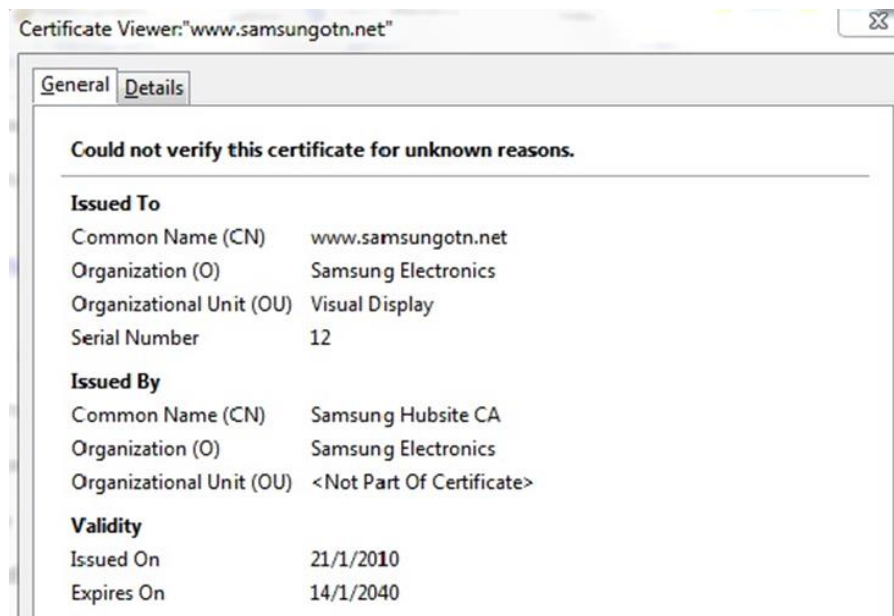

Firmware files downloaded via the online procedure are not signed. So, by decrypting, modifying and then re-encrypting the firmware someone can easily update the TVs firmware with his own customized version. However, creating a customized version is very dangerous, considering the possibility of getting your Samsung TV “bricked”. “Brick” is a term used by the hacking community when a device is not operational due to a software update failure. Assuming that the customized Firmware was developed correctly, you can update the TV through the online update procedure.

### 3.1.4 Attack Procedure

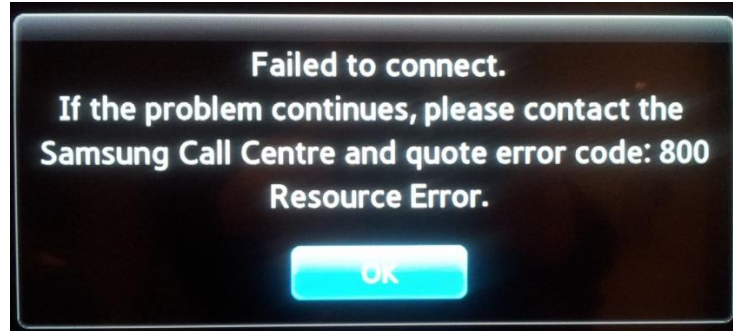

Based on Wireshark, it was found that the online update procedure starts with a TLS/SSL connection with [www.samsungotn.net](http://www.samsungotn.net).

Figure 9: samsungotn.net certificate

The certificate is signed with Samsung Hubsite private key. Using Burp Suite, a Man in The Middle attack (MiTM) was performed, yet the TV popped up a network error due to the denial of Burp Suite’s self-signed certificate.

Figure 10: Certificate Denial

Looking up closely at the captured communication between the two entities (Samsung TV – Samsung Web Server), it was discovered that after this initial HTTPS connection with [www.samsungotn.net](http://www.samsungotn.net), a HTTP (unsecure) connection was established with the same webserver for checking the availability of a new update (Figure5). Afterwards, another HTTP connection was established with “az43064.vo.msecnd.net” to actually download the firmware files (Figure 6).

Figure 11: Unsecure firmware update check

  ▶ GET /firmware/tv/154/SWU_T-MST10PDEUC_001031_I04_KS000RS000ES000DS000_121129/appext.img HTTP/1.1\r\n
    Host: az43064.vo.msecnd.net\r\n
    Accept: */*\r\n
    \r\n
```

Based in the above facts we added a static DNS entry to the “hosts” file in order to forward the HTTP GET request to a local Web Server, running on the other laptop, instead of Samsung update Web Server (az43064.vo.msecnd.net). Furthermore, by using the download link<sup>6</sup> provided by Wireshark captured file, the first file (appext.img) needed for the upgrade process was downloaded. The only thing missing was to test whether the download procedure would accept the file that was provided by our Apache Web Server. As expected the file was successfully accepted. (Figure 7 – 8)

Figure 13: Local server update

## ***3.2 Browser Attack***

### ***3.2.1 Browser Importance***

Browsers are the fundamental applications that any “Smart” OS can provide, considering that the terminology Smart derives from the fact that it interacts with the internet. On the other hand, most of the services that web browsers provide (for Smart OSs) have been replaced by the apps in terms of speed and user-friendliness. Samsung Apps (store) is still at an early stage of development and either popular apps are missing or they exist with limited functionality. Hence, most of the interaction with internet has to be done through the browser and with the ease provided by a USB keyboard/mouse.

### ***3.2.2 About the browser***

The browser is based on an outdated version of Firefox (version 5, based on user strings) and supports basic extensions like Java, flash and can also manage cookies. Moreover, it supports SSL/TLS over HTTP.

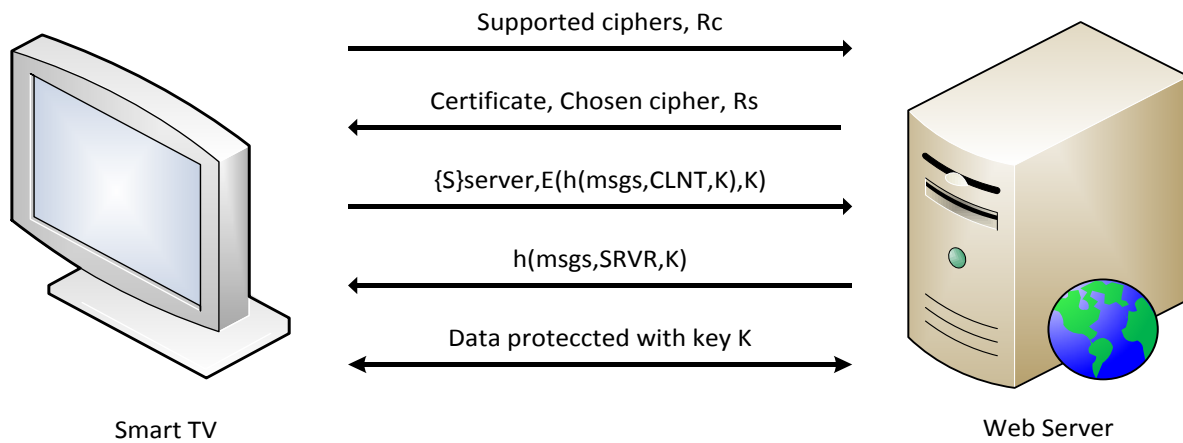

### ***3.2.3 SSL/TLS background***

SSL is designed to run on top of layer 4 and provides a reliable encrypted and integrity protected TCP connection to the application. The main operation is described below:

1. The client contacts the server, gives out the list of cryptographic algorithms supported and a random number  $R_c$ .
2. The server sends his certificate, plus the highest algorithm that they both support and also a random number  $R_s$ .
3. If the client accepts (trusts) the certificate (contains server's public key), the client chooses a random number  $S$  and encrypts it by using the public key. Along with the encrypted random number  $S$ , the client also sends an encrypted keyed hash, of the master secret  $K=h(S,R_c,R_s)$  and the handshake messages.
4. The server proves that it knows the session keys and ensures that the previous messages arrived intact by sending back a keyed hash of all the previous messages plus the master secret  $K$ .

- The connection is established and protected with master key  $K$  until the session is terminated.

Figure 15: TLS/SSL

### 3.2.4 Man in the Middle Attack (MiTM)

The most common attack for the SSL is Man in the Middle attack. The method is described in the following figure:

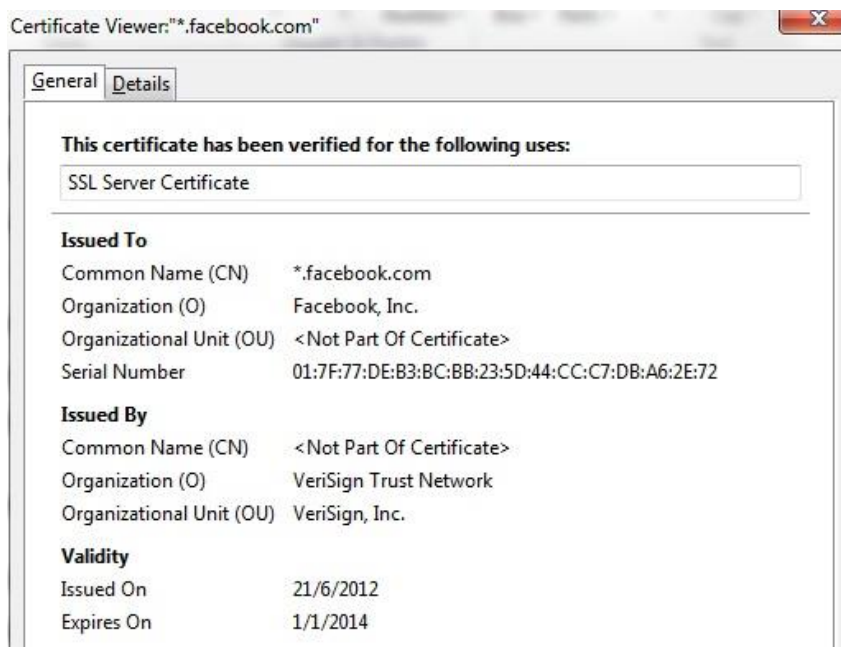

Figure 16: TLS/SSL MiTM

The client establishes an SSL connection with the attacker, by using master key  $K1$  after its certificate is accepted by the client. In the meantime the attacker establishes a SSL connection to

the server that the client has intention to connect using a master key K2. Now, the attacker can read or modify any conversation exchanged between the client and the server. This type of attack can be prevented by automatically checking the validity of the certificate. If this is not the case the user must be always asked whether the certificate should be trusted or not.

Figure 17: Certificate example

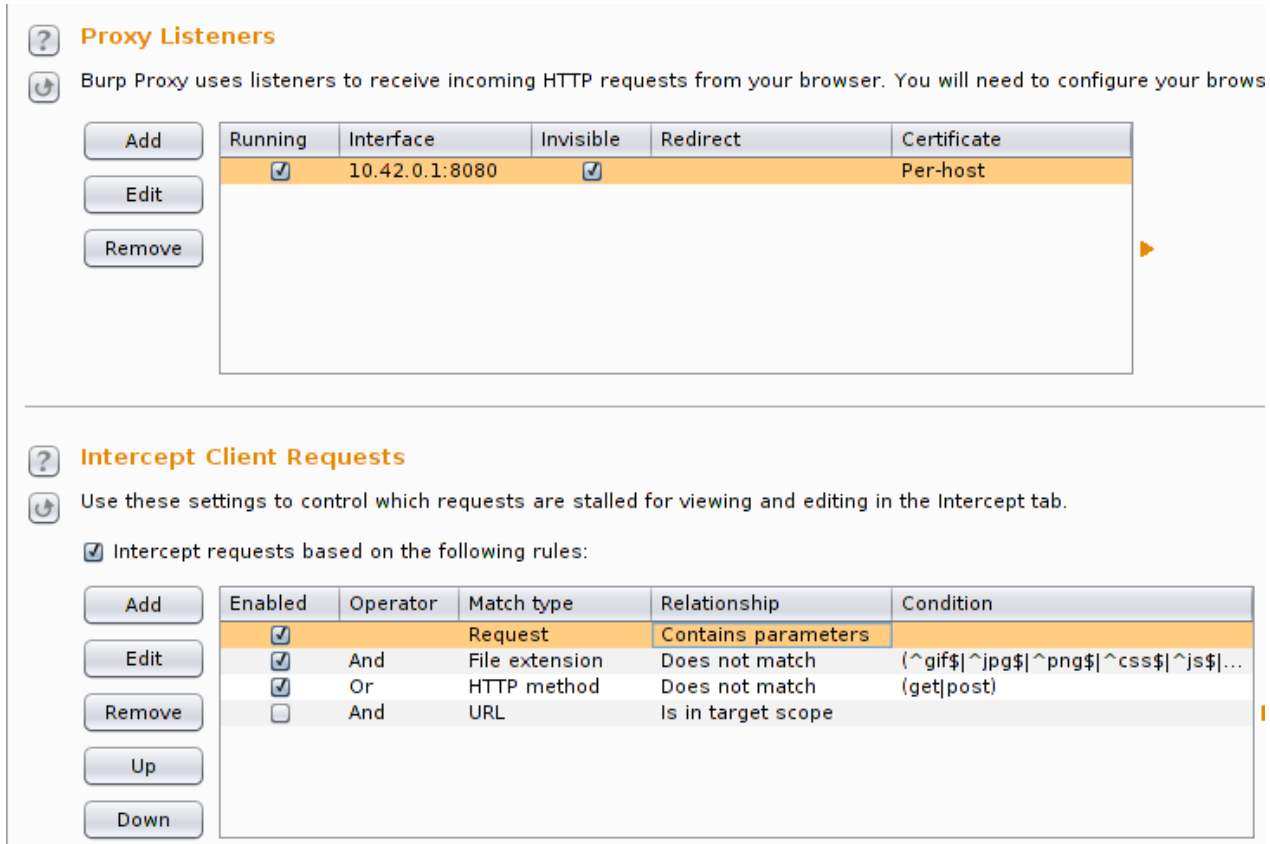

A SSL server certificate contains the public key of the server, the common name of the server, the starting day of the validity and the expiration day, all signed by a Certificate Authority. A common browser has pre-installed certificates of trusted Certificate Authorities in order to check the validity of any given certificate. Furthermore, it verifies if the requested domain matches the CN that the certificate is signed for and also checks whether the duration that the certificate is valid for, matches the local time.

### 3.2.5 Attack Procedure (SSL MiTM)

In order to apply such a MiTM attack, a proxy server (Burp Suite) with a self-signed certificate was used. As it is depicted, the Samsung Laptop plays the role of a router. Through

iptables configuration<sup>7</sup> packets whose source IP is equal to the TV’s IP and whose destination port is equal to “443” are forwarded to port 8080, on “eth0” that Burp Suite listens.

Figure 18: Burp Suite proxy

The idea behind this MiTM attack is to check whether Samsung’s browser checks for trusted SSL certificates when going to a secure HTTPS website. So, a site that supports HTTPS connection and its certificate is signed by a trusted authority (VeriSign) was typed in: <https://www.facebook.com/>. The TV’s browser, establishes an HTTPS connection with Burp Suite by accepting (without user verification) the Burp Suite’s self-signed certificate. Then, the specific HTTPS GET request is being forwarded by Burp Suite to Facebook.

<sup>7</sup> sudo iptables -A PREROUTING -t nat -i eth0 -p tcp --dport 443 -s 10.42.0.53 -j REDIRECT --to-port 8080

Figure 19: Decrypted HTTP GET message

The response also passes through Burp Suite and the login page appears in Samsung's browser.

Figure 20: Facebook login page

Furthermore, a small lock badge shows up in the toolbar, indicating a false notification that a secure connection is established with the specific site. Next, the demo credentials are typed in, and Burp Suite intercepts all the traffic that is being sent.

Figure 21: Decrypted HTTP POST message

```

gnjs=1359485758&locale=en_US
```

It is possible to modify the request/response, sent/received through Burp Suite and enhance the attack. As depicted from the above figure, both the user name and password appear, verifying a successful MiMT.

## 3.3 Miscellaneous Attacks

### 3.3.1 Samsung Apps

The third most important part of the TV in terms of security is the applications. Samsung has its own app-store called Samsung Apps through which you can install, update and uninstall the apps. Regarding the security, there are two questions that can be raised: What are the privileges of the apps over the system? How difficult is it for an outsider to create and install a malicious application in the TV?

Samsung only permits apps written in JavaScript/HTML/Flash<sup>8</sup> through its own SDK<sup>9</sup>. In JavaScript there are several APIs that are offered for I/O, video, audio, camera and also open/close/delete/create operations, which all work in a shared directory “/mtd\_rwcommon”. There is only one user found, namely the root user. So, based on the shared folder concept, every app can actually have access to the files that other apps create. Hence, by taking advantage what Samsung permits in terms of file access, an attacker can create a malicious app and affect every other app installed in the same system<sup>10</sup>.

Recently SammyGo community released an application that gives you remote shell access using an app and a usb stick containing scripts<sup>11</sup>. In order to install this app you have to be logged in as a developer and configure the TV to synchronize user apps from SammyGo webserver (149.154.159.134). After this synchronization, the app *Test2* is installed to the TV and as illustrated in Figure 22, a user indication exists to point out that the application is installed in developer mode. Then you have to run the application with the usb stick plugged in and open the browser. After those steps a shell access is provided by using *nc* on port 23.

---

<sup>8</sup> <http://www.samsungdforum.com/Devtools/Spec>

<sup>9</sup> <http://www.samsungdforum.com/Devtools/SdkReleaseNote>

<sup>10</sup> <http://www.samsungdforum.com/Guide/ref00001/index.html>

<sup>11</sup> <http://forum.samygo.tv/download/file.php?id=1509>

Figure 22 Test2 app

The app essentially copies from the usb stick a modified library “*libm.so.6*” to the filesystem of the TV by using the following method “`eval("FilePlugin.Copy(\"/dtv/usb/sda1/libm.so.6\", \"/dtv/libm.so.6\")");`”. This command proves that the sandbox of the “*mtd\_rwcommon*” area is broken given that it can actually write on the restricted “/dtv” folder. When you open the browser, the script “`/dtv/usb/sda1/bin/run.sh`” (Figure 23) runs and provides shell and ftp access. This is done by installing a busybox (richer than the one installed on the TV) on the /tmp/bin folder. Finally by adding the following lines to the script it is possible to write the results of commands “netstat”, “ps”, “dmesg” to log files on the usb stick. The results are provided to the Appendix. Also by adding “`kill all 68`” ( 68 process is exeDSP) the TV **freezes** and **reboots**.

```
mkdir /tmp/os3
chmod 777 /tmp/os3
netstat -tulpn > /tmp/os3/netstat.log
ls -alt / > /tmp/os3/ls_root.log
ls -alt /bin >> /tmp/os3/bin.log
ps >> /tmp/os3/ps.log
dmesg > /dtv/usb/sda1/from_tv/dmesg.log
cp -r /tmp/os3/* /dtv/usb/sda1/from_tv/
```

Figure 23 go.sh

```
#!/bin/sh

cd /tmp
mkdir /tmp/bin
cp /dtv/usb/sdal/bin/* /tmp/bin/
chmod 777 /tmp/bin/*
/tmp/bin/busybox --install -s /tmp/bin
sync
export PATH=/tmp/bin:$PATH
export LD_LIBRARY_PATH=/tmp/bin:$LD_LIBRARY_PATH
sync
/tmp/bin/busybox tcpsvd -vE 0.0.0.0 21 /tmp/bin/busybox ftpd -w / &
/tmp/bin/remshd &
sync
sleep 10
```

However, this cannot be considered as a remote attack because the attacker has to have physical access in order to use the usb ports of the TV and login as a developer. There is only one (legit) way to install an app to a Samsung Smart TV is by downloading it from the Samsung store. In this case, Samsung needs to approve that your app is secure before it can be publicly available. It was impossible to determine how Samsung does this evaluation and in what depth the application is checked for security flaws. The last thing that needs to be checked is how the install/update procedure from Samsung apps is performed.

▼ Authoritative nameservers

From the below picture it can be derived that use of “Samsung apps” demand an HTTPS connection.

Figure 25: TLS/SSL certificate

The certificate is signed with DigiCert’s private key. Using Burp Suite, a Man in The Middle attack (MiTM) was attempted, yet the TV popped up a “Network interference” error due to the denial of Burp Suite’s self-signed certificate.

Figure 26: Network interference error

So a hacker cannot impersonate “Samsung apps” Web service unless he possesses the private key.

### 3.3.2 Remote help service

Samsung's OS provides a special service for remote management to help customers with troubleshooting. This is done by manually selecting this service from the support menu and only after the customer accepts the privacy agreement. Then a random pin number pops up to be verbally passed to the engineer who will check for any malfunctions. The specific service was started, while Zenmap rescanned the ports. It was noticed that there were no additional ports opened. Likewise, another session was initiated, but this time the network traffic was captured. It showed that there was a secure TCP connection with Samsung headquarters.

Figure 27: HTTPS connection with samungrm.net

Once again, the Web Server's certificate was signed by Samsung Hubsite CA and we verified that the TV checks the validity of the certificate that is provided.

Our hypothesis is that this secure connection, which is a reverse connection, works in the same way as various remote control services that have to bypass any firewall. We suspect that the pin-code is an identifier for the Samsung engineer to distinguish the customer's request for help.

Figure 28: HTTP POST pin-code

123	63.5810.42.0.53	54.243.241.75	HTTP	411	POST /rm/notice HTTP/1.1 (application/x-www-form-urlencoded)

```
# Frame 123: 411 bytes on wire (3288 bits), 411 bytes captured (3288 bits) on interface 0
# Ethernet II, Src: SamsungE_e3:f1:4b (1c:5a:3e:e3:f1:4b), Dst: Wistron_6a:26:93 (00:1f:16:6a:26:93)
# Internet Protocol Version 4, Src: 10.42.0.53 (10.42.0.53), Dst: 54.243.241.75 (54.243.241.75)
# Transmission Control Protocol, Src Port: 45946 (45946), Dst Port: http (80), Seq: 1, Ack: 1, Len: 345
# Hypertext Transfer Protocol
# Line-based text data: application/x-www-form-urlencoded
  \357\273\277<?xml version="1.0" encoding="UTF-8" ?>\n
  <reconnection>\n
  <status>activate</status>\n
  <pincode>11685618</pincode>\n
  <version>2.3</version>\n
  </reconnection>\n
```

This pin though is sent in clear text, but this would not imply that this is a bad implementation in terms of security. Unfortunately, it cannot be stated that is secure either. It was impossible to communicate with Samsung’s remote assistant service in order to establish a session; due to its high demand and lack of availability. Hence, capturing the network traffic data was infeasible. This remote service might hide a vulnerability that must be researched in depth.

### 3.3.3 AllShare

AllShare is a service that is used to share contents within a Local Area Network (LAN) with DLNA compliant devices. DLNA stands for Digital Living Network Alliance and uses UPnP for media management discovery and control.

For this service, the TV uses the 55000 and 55001 ports and the traffic is unencrypted since the DLNA protocol does not support encryption<sup>12</sup>. This cannot be considered as a security issue but a design feature. It should be mentioned that a typical authentication (hostname, ip-address) is being used, so when a media server wants to connect to the TV for the first time a pop up dialog box appears on the TV screen to accept or reject access.

---

<sup>12</sup> <http://www.dlna.org/>

### 3.3.4 Remote control

There are several apps for Smart Phones, Tablets and PCs which act as virtual remote control that operate through the network. For this service, the TV uses DLNA protocol at port 55001. As previously mentioned, this protocol uses primitive authentication and does not support encryption. Thus, someone can easily impersonate an already accepted device.

Our purpose was to investigate the type of security that the TV provides while adding a new software remote control device. Every time the user adds a new remote device to the TV, the system via AllShare sends a notification-confirmation message (Allow/Deny) along with the device's hostname. It is up to the user to accept or deny the device. After this authentication mechanism the software remote control identifies itself to the AllShare control panel. In order to demonstrate the vulnerability of the authentication mechanism, SSRemote software was used. The first thing to do is to configure the SSRemote (v0.5) to connect to the TV and then just accept it through AllShare confirmation message. As it is depicted on Figure 29 the SSRemote identifies itself with the strings "SSRemote\_V05" and "SSRemote\_IP" for hostname and IP respectively. By repeating the same procedure from another host we could easily remote control the TV simultaneously without the need of verification. This occurs due to the fact that the second instance provides the same strings as credentials which bypass the authentication procedure. Provided that the hostname and the IP of an authenticated device can easily be sniffed, it is possible to spoof any remote control device. ([Video of Attack Demonstration](#))

Figure 29 AllShare settings

### 3.3.5 Web Server

For no apparent reason there is a Web Server (lighttpd) running on ports 80, 443 and 4443. During the black box approach different kinds of tools (web crawlers, web vulnerability

scanners) were used to stress test the lighttpd daemon. Nikto and DirBuster did not give any valuable results yet the following ssl-dos attack did.

```
thc-ssl-dos -n 800 10.42.0.53 443
```

```
....  
Handshakes 48 [47.98 h/s], 462 Conn, 0 Err  
....  
Handshakes 219 [40.89 h/s], 474 Conn, 0 Err  
Handshakes 297 [78.16 h/s], 474 Conn, 0 Err  
....  
Handshakes 16500 [77.36 h/s], 536 Conn, 0 Err  
Handshakes 16569 [69.50 h/s], 536 Conn, 2 Err  
Handshakes 16648 [78.95 h/s], 536 Conn, 2 Err  
Handshakes 16719 [70.30 h/s], 536 Conn, 2 Err  
Handshakes 16796 [77.66 h/s], 536 Conn, 2 Err  
Handshakes 16867 [71.25 h/s], 535 Conn, 4 Err  
....  
Handshakes 19294 [76.06 h/s], 542 Conn, 12 Err  
Handshakes 19372 [75.22 h/s], 543 Conn, 12 Err  
Handshakes 19452 [82.50 h/s], 543 Conn, 12 Err  
....  
Connection timed out  
Connection timed out  
Connection timed out
```

In the above script we set an upper limit of parallel connections equal to 800. The script starts with the minimum of ~460 parallel connections and increments up to 800, while keeping an average rate of 65 handshakes per second for the whole session. As it is depicted, after the 16500th connection lighttpd starts returning errors (2 Err). At some point (after 60s) the server cannot handle any of the incoming connections; hence returning "connection time out". At this point the server becomes non-operational.

When the decrypted firmware was available, it was possible to read the configuration file of the Web Server.

```
#  
# Security hardening  
#  
# Give another name to the server, we dont want hackers to know which server we use  
server.tag="Swift1.0"  
  
# Prevent access to all files except the virtual folders which are supported  
$HTTP["url"] !~ "^/(|$|www/|ws($|/)|api($|/)|test($|/)|dtv/usb($|/)|dev($|/))" {  
    url.access-deny = ("")  
}
```

With the above regular expression the Web Server prevent us from having access to anything except folders “/”, “/ws”, “/api”, “/test”, “/dtv/usb” and “/dev”. A tcpdump session was scheduled to run for eight hours, yet we did not observe any local traffic.

### ***3.3.6 Other Network related daemons***

There are other 4 tcp ports open (7676, 6000, 3697 and 9090) besides the ports used for lighttpd and DLNA (80, 443, 4443, 55000 and 55001). Likewise, a tcpdump session was scheduled to run for eight hours, yet no connection was established in these ports. We did not observe any local traffic in this case either.

### 3.3.7 Popular installed apps

The most important and popular apps were checked for flaws. In our perspective, these would be all the social apps, Skype, Facebook, Twitter and some popular apps in the Netherlands like Pathé. For all the aforementioned applications, it was checked whether the communication protocol that they use was secure. All of them use a SSL/TLS connection and after thorough checking it was determined that SSL/TLS was implemented properly. Pathé app does not use an SSL/TLS and sends sensitive data in clear text (email=donpsol%40gmail.com & password=aibjckdl) as it is depicted from the following figure.

Figure 30: Pathé HTTP POST

The screenshot shows a web proxy tool interface with the following elements:

```

## *4 Discussion*

During the assessment of Samsung TV, we identified the following design flaws.

### *1<sup>st</sup> Design flaw*

It has already been stated that by changing only a DNS response you can upgrade the firmware of the TV from a non-authentic Samsung Web Server. Due to the simplicity of this attack and the fact that it can be performed in a single or in a larger scale (i.e. DNS poisoning, Rogue DHCP Server) the consequences can be severe. Indeed by creating a custom firmware a potential hacker can deliver it through the update procedure without the user noticing it. **A custom firmware might be either a modified firmware that gives the attacker access to the TV (mic/camera/sensitive data) or a firmware that has been deliberately misconfigured to force the TV in a non-operational state.**

### *2<sup>nd</sup> Design flaw*

For a smart device, a browser is indispensable let alone when it's pre-installed (no uninstall option) and the only available for Samsung Smart TVs. It is proven that the browser does not check the validity of the SSL certificates. Going to a secure site (HTTPS) there is a lock indicating that the user's data are under a secure channel, yet this is not the case. Indeed, **not only you can read but also modify the exchanged packets without the user noticing it.** We are talking about Samsung branded, Firefox based browser that should be updated to the latest version, or at least the next firmware should include the CA certificates pre-installed.

### *3<sup>rd</sup> Design flaw*

The fact that there is only one user in the system, "root" and also that all application files share a common folder makes the TV vulnerable. Considering the situation that there is one vulnerable application running, **an attacker can exploit this application and compromise the whole TV.** The only countermeasure is the application certification procedure (beforehand) where Samsung checks the application for malicious content. At what depth does Samsung check the security risks that one app might carry is really unknown.

#### ***4<sup>th</sup> Design flaw***

Samsung uses DLNA protocol for both video/audio streaming and remote control feature. DLNA was designed to be unencrypted, but the idea of using an unsecure protocol for the Remote control service is considered inadequate. A possible negative outcome of this design flaw would be for example to present inappropriate video content in a common public area like café/office/class. A new secured protocol should be designed for remote control service thus providing the user a more risk-free remote session.

## ***5 Conclusion***

There were several countermeasures that were implemented by Samsung for many of the services provided, in order to offer a secure environment for the users. Yet in some cases, these were proven to be insufficient. In particular, the firmware by itself is encrypted by AES+XoR, but the keys have already been found, making the firmware modification possible. In addition, based on the attack method described, an upgrade with a modified firmware can be done remotely.

Moreover, this Smart TV system supports SSL/TLS protocol which, in most cases, is successfully implemented with one exception, the browser. The browser accepts any SSL certificate that makes it susceptible to a Man in The Middle Attack without the user's notice.

Regarding the Samsung Apps repository, the downloading procedure is performed through a secure connection with Samsung's servers that provide only apps which are already approved by Samsung. It wasn't possible to determine the level of security check that is being applied to apps, given that there was no time creating a malicious one and waiting to be approved or rejected. The security policy applied by Samsung was to create a Sandbox with which a app can only write/read from a specific folder and not outside of it. This policy however, was proven to be violated by using a Javascript method which copies files from a source to a destination outside the sandbox.

Finally, some popular and preinstalled apps were checked in terms of the communication protocol being used and all of them were found secure except "Pathé".

## ***6 Future Work***

There are quite a lot of areas that can be investigated and considered as a future work, considering we are talking about a new commercial product equipped with various network services.

### ***Create a Custom Firmware***

Create a custom Firmware that provides remote shell access to the TV and distribute it through our “Attack Procedure”.

### ***Check Remote Help Service***

It is intriguing to actually eavesdrop the communication between the TV and the Samsung support center during this Remote Help Service, since it could reveal a serious vulnerability.

### ***Root ES models in a remote way.***

The possibility of rooting the TV remotely and enabling shell access would mean taking the full control of the TV in a stealthy way.

### ***Check Broadcast update.***

It is very interesting that Samsung has enabled this feature and moreover it would be no surprise if there is weak or no security at all for this procedure. With the current available tools, someone can create a legitimate look-alike firmware, where a hacker can create a multi-attack scheme through broadcasting.

### ***Further investigation about daemons***

There were 4 different ports open whose existence and functionality were unclear. Ports 9090, 3697, 7676, 6000.

### ***Samsung TV apps security check assessment.***

Develop a Trojan horse and check whether Samsung accepts it for the Samsung TV App store.

***Unclear Web Server existence***

Find what lighttpd is used for. It runs in 80 & 443/4443 ports.

# Appendix

## Nessus

Figure 31: Nessus Summary

Summary					
Critical	High	Medium	Low	Info	Total
0	0	4	2	21	27
Details					
Severity	Plugin Id	Name			
Medium (6.4)	51192	SSL Certificate Cannot Be Trusted			
Medium (4.3)	42873	SSL Medium Strength Cipher Suites Supported			
Medium (4.3)	53491	SSL / TLS Renegotiation DoS			
Medium (4.0)	35291	SSL Certificate Signed using Weak Hashing Algorithm			
Low (3.2)	50686	IP Forwarding Enabled			
Low (2.6)	10407	X Server Detection			
Info	10107	HTTP Server Type and Version			
Info	10114	ICMP Timestamp Request Remote Date Disclosure			
Info	10287	Traceroute Information

usb 3-1.3: SerialNumber: 4C532000030128123255
usb 3-1.3: usb_probe_device
usb 3-1.3: configuration #1 chosen from 1 choice
usb 3-1.3: adding 3-1.3:1.0 (config #1, interface 0)
usb-storage 3-1.3:1.0: usb_probe_interface
usb-storage 3-1.3:1.0: usb_probe_interface - got id
scsi0 : usb-storage 3-1.3:1.0
drivers/mstar/usb/core/inode.c: creating file '003'
hub 3-1:1.0: state 7 ports 4 chg 0000 evt 0008
scsi 0:0:0:0: Direct-Access SanDisk Cruzer Pop 1.26 PQ: 0 ANSI: 5
sd 0:0:0:0: [sda] 31266816 512-byte logical blocks: (16.0 GB/14.9 GiB)
sd 0:0:0:0: [sda] Write Protect is off
sd 0:0:0:0: [sda] Mode Sense: 43 00 00 00
sd 0:0:0:0: [sda] Write cache: disabled, read cache: enabled, doesn't support DPO or FUA
sda: sda1
sd 0:0:0:0: [sda] Attached SCSI removable disk
Poller thread started for sda, PID = 609
FAT: utf8 is not a recommended IO charset for FAT filesystems, filesystem will be case sensitive!
hid mod ld
usbcore: registered new interface driver usbhid
usbhid: USB HID core driver
usbhid mod ld
evdev mod ld
mice: PS/2 mouse device common for all mice
mousedev mod ld
hid_microsoft mod ld
[CIP_KERNEL] (1)th waiting.
[CIP_KERNEL] authentication success!!!
[CIP_KERNEL] Success!! Authuld is successfully completed.
